Download the modification for 0.50\$ for online or offline Q: Can a Model in Django-REST-Framework represent more than one model? I have a problem and I'm not sure how to handle it in a RESTful way. I have a model that represents points of interest. It has the following fields: title = models.CharField(max\_length=255) coordinates = models.PointField(srid=4326, blank=True, null=True) Then, I have a model that represents a place. it has the following fields: name = models.CharField(max\_length=255) I'm wondering if it would be possible to create a Model in Django-REST-Framework that has two Model's inside. I could create something like: class PlaceDetails(Model): place = models.ForeignKey(Place) place\_id = models.IntegerField() But is there a way to reference two models inside a single Model? I'm thinking that my JSON response would look something like this: { "place\_details": [ { "title": "MyTitle", "coordinates": "POINT (XXXXX XXXXXX)", "name": "MyName" } ] } A: You can access to the fields of the other model like this: title = models.CharField(max\_length=255) coordinates = models.PointField(srid=4326, blank=True, null=True) name = models.CharField(max\_length=255) Protocol Address Verification Features Protocol Address Verification is a feature of the web application that checks whether the IP of the user has changed 82157476af
